

Contact between majority and minority social groups is negative for the latter

06/02/2020

An international study, in which the University of Granada (UGR) participated, has confirmed that intergroup contact between advantaged groups (ethnic majorities and cis-heterosexuals) and disadvantaged groups (ethnic minorities and sexual minorities) is not always positive as a strategy for reducing prejudice toward disadvantaged groups, contrary to the view traditionally defended in the Social Psychology field.

The research, published recently by the journal *Nature Human Behavior*, notes that, for minority groups, this contact seems to be negatively related to support for social change toward greater equality.

The team led by Tabea Hässler and Johannes Ullrich of the University of Zurich (Switzerland) coordinated an international study conducted jointly by academics from 69 countries, in which data was collected from advantaged groups (ethnic majorities and cis-heterosexuals) and disadvantaged groups (ethnic minorities and sexual minorities). By means of international coordination, data was obtained from a total of 12,997 people from different groups and countries.

The results show that, for people who belong to a majority (for example, heterosexuals), contact with a minority group (for example, LGTBI people) fosters support for social equality. The greater the degree of contact, the greater the support for disadvantaged groups.

By contrast, for minority groups, intergroup contact and support for social change toward greater equality appear to be negatively associated. That is, intergroup

contact in this case makes people who belong to minorities less supportive of equality (even though, a priori, equality is something that benefits them as a group).
